### Chapter 6

# Supervised machine learning for categorical data

Professor Jung Jin Lee Soongsil University, Korea New Uzbekistan University, Uzbekistan Chapter 6 Supervised machine learning for categorical data

6.1 Basic concept of supervised machine learning and classification model

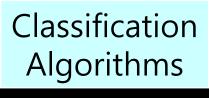

- 6.2 Decision tree model
- 6.3 Naive Bayes classification model
- 6.4 Evaluation and comparison of classification model

### Classification:

- Predicts categorical class labels
- Classifies data (constructs a model) based on the training set and the values (class labels) in a classifying attribute and uses it in classifying new data
- Typical Applications
  - credit approval
  - target marketing
  - medical diagnosis
  - treatment effectiveness analysis

- Model construction: describing a set of predetermined classes
  - Each data is assumed to belong to a predefined class
  - The set of sample data used for model construction: training set
  - The model is represented as classification rules, decision trees, or mathematical formulae
- Model usage: for classifying unknown objects
  - Estimate the accuracy of the model
    - The known class label of a test sample is compared with the classified result from the model
    - Accuracy rate is the percentage of test set samples that the model correctly classifies
    - Test set is independent of training set, otherwise over-fitting will occur

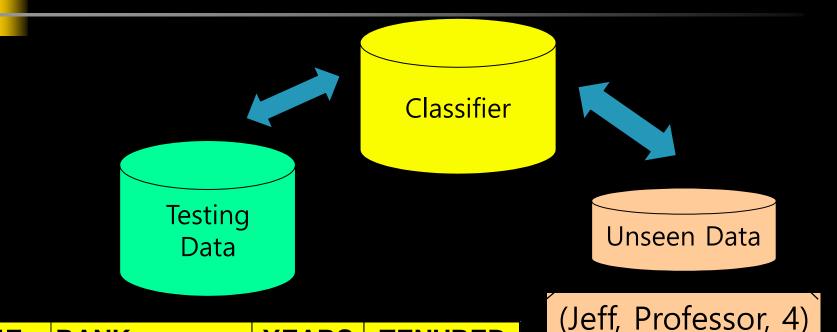

| NAME | RANK           | YEARS | TENURED |
|------|----------------|-------|---------|
| Mike | Assistant Prof | 3     | no      |
| Mary | Assistant Prof | 7     | yes     |
| Bill | Professor      | 2     | yes     |
| Jim  | Associate Prof | 7     | yes     |
| Dave | Assistant Prof | 6     | no      |
| Anne | Associate Prof | 3     | no      |

Classifier (Model)

IF rank = 'professor' OR years > 6 THEN tenured = 'yes'

| NAME    | RANK           | YEARS | TENURED |
|---------|----------------|-------|---------|
| Tom     | Assistant Prof | 2     | no      |
| Merlisa | Associate Prof | 7     | no      |
| George  | Professor      | 5     | yes     |
| Joseph  | Assistant Prof | 7     | yes     |

#### Supervised learning (classification)

- Supervision: The training data (observations, measurements, etc.) are accompanied by labels indicating the class of the observations
- New data is classified based on the training set
- Unsupervised learning (clustering)
  - The class labels of training data is unknown
  - Given a set of measurements, observations, etc. with the aim of establishing the existence of classes or clusters in the data

#### General process of classification

Data cleaning and division Collect data from each group, clean and transform it, and divide the data into training and test data.

↓ ↑

Training the model Establish a classification model  $y = f(m{x})$  using the training data.

, ↑

Validation of the model Validate the classification model using the testing data.

#### Apply the model

Classify data whose group affiliation is unknown into one group using the classification model.

- General process of classification
- Data cleaning
  - Preprocess data in order to reduce noise and handle missing values
- Relevance analysis (feature selection)
  - Remove the irrelevant or redundant attributes
- Data transformation
  - Generalize and/or normalize data

#### Evaluating classification model

Table 6.1.1 Table for the test results of the actual group and the classified group

|              |       | Classifie   |          |                   |
|--------------|-------|-------------|----------|-------------------|
|              |       | $G_1$       | $G_2$    | Total             |
| Actual group | $G_1$ | <b>f</b> 11 | $f_{12}$ | $f_{11} + f_{12}$ |
|              | $G_2$ | $f_{21}$    | $f_{22}$ | $f_{21} + f_{22}$ |
|              | Total |             |          | n                 |

$$egin{aligned} ext{Accuracy} &= rac{f_{11}+f_{22}}{n} \ ext{Error rate} &= rac{f_{12}+f_{21}}{n} \ n \end{aligned}$$

- Spliting method for training and testing data
- Holdout method
  - divides the entire data set into two non-overlapping data sets and holding out one as training data and the other as testing data. (1/2 training, 1/2 testing)
  - Repeat r times and calculate the average accuracy.

$$ext{Overall accuarcy} = rac{1}{r} \Sigma_{i=1}^r (Accuracy)_i$$

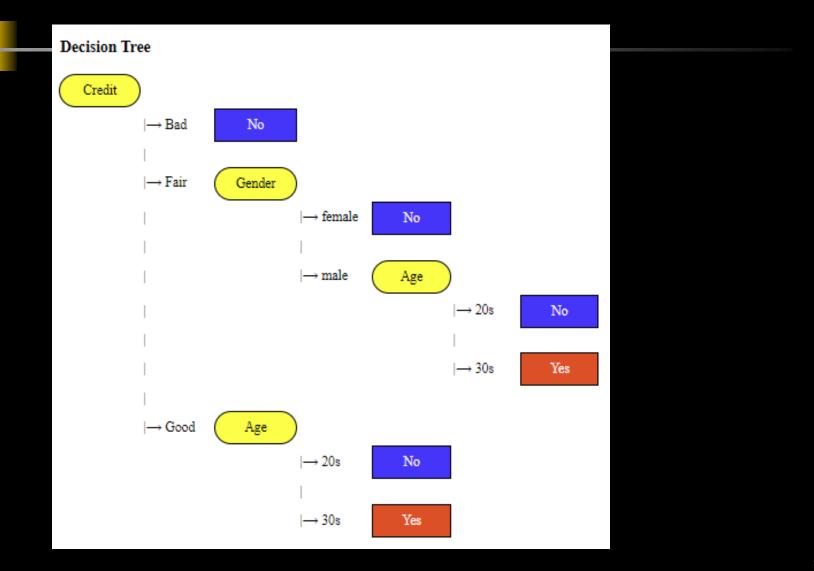

- Cross validation method
  - Change the role of training and testing data
  - K-fold cross validation is possible

Spliting method for training and testing data

- Bootstrap method
  - Sampling with replacement for training data
  - If the total number of data is N, the number of sample extracted for training data using the bootstrap sampling is 63.2% in average
  - Probability that each data is selected by the bootstrap sampling is 1 (1 1/N)^N

#### Decision Tree

- tree-shaped drawing of a classification function consisting of decision rules
- Ovals represent nodes: tests for variables top node: root node
- Branches: values of the tested variables
- Rectangles: final classified groups which are called leaves

### Decision tree algorithm

- The number of cases for creating a decision tree is exponentially proportional to the number of variables and values of each variable
- How do you quickly find a decision tree with high classification accuracy?
- It is not easy to find the global optimum in the entire number of decision tree cases
- We create an algorithm that is locally optimal
  - => Form a decision tree by selecting the optimal variable at each node

### Decision tree algorithm

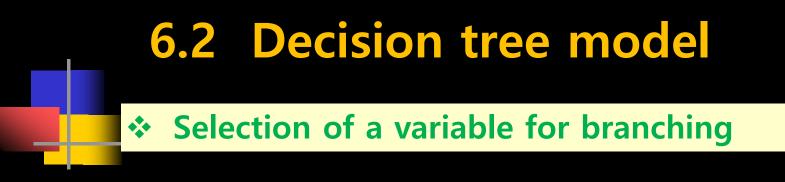

✤ E = {data 집합} F = {변수집합}

```
TreeGrowth (E, F)
Step 1: if stopping_condition(E, F) = true then
Step 2:
             leaf = creatNode().
Step 3: leaf.label = Classify(E)
Step 4:
          return leaf
Step 5: else
Step 6:
             root = creatNode()
Step 7:
             root.test_condition = find_best_split(E, F)
             let V = {v : v is a possible outcome of root.test_condition}
Step 8:
             for each v \in V do
Step 9:
Step 10:
                 E_v = \{ \{ \text{root.test\_condition}(e) = \} \cap \{ e \in E \} \}
Step 11:
                 child = TreeGrowth(E_v, F)
Step 12:
                 add child as descendent of root and label the edge(root 
ightarrow child) as v
Step 13:
              end for
Step 14: end if
Step 15: return root
```

### Selection of a variable for branching

| Table  | e 6.2.1 Crosstable of Gender b | y Purchase and Non-purchasing grou | р     | Table 6.2.2 Crosstable of Credit status by Purchase and Non-purchasing group |                        |                            |       |
|--------|--------------------------------|------------------------------------|-------|--|------------------------|----------------------------|-------|
| Gender | Purchasing group $G_1$         | Non-purchasing group $G_2$         | Total | Credit Status  | Purchasing group $G_1$ | Non-purchasing group $G_2$ | Total |
| Male   | 4                              | 6                                  | 10    | Good   | 7                      | 3                          | 10    |
| Female | 4                              | 6                                  | 10    | Bad  | 1                      | 9                          | 10    |
| Total  | 8                              | 12                                 | 20    | Total  | 8                      | 12                         | 20    |

- Gender: ratio of (Purchasing:Nonpurchasing) are the same (4:6) in males and females
- Credit status: Good (7:3), Bad (1:9)
- Selecting Credit Status will increase the classification accuracy.

- At each node, select a variable using
  - chi square independence test
  - entropy coefficient
  - Gini coefficient
  - classification error rate

#### Selection of a variable for branching

#### A. Chi-square independence test

Table 6.2.3 Observed frequencies of a variable A by Purchase status group

| Variable $A$ value | Purchasing group $G_1$ | Non-purchasing group $G_2$ | Total                   |
|--------------------|------------------------|----------------------------|-------------------------|
| $A_1$              | O <sub>11</sub>        | $O_{12}$                   | <i>O</i> <sub>1</sub> . |
| $A_1$              | $O_{21}$               | $O_{22}$                   | <i>O</i> <sub>2</sub> . |
| Total              | $O_{\cdot 1}$          | $O_{\cdot 2}$              | О                       |

Table 6.2.4 Expected frequencies of a variable by Purchase status when they are independent

| Variable $A$ value | Purchasing group $G_1$                                      | Non-purchasing group $G_2$                                  | Total                   |
|--------------------|---|---|-------------------------|
| $A_1$              | $E_{11}=O_{1\cdot}	imes rac{O_{\cdot 1}}{O_{\cdot \cdot}}$ | $E_{12}=O_{1\cdot}	imes rac{O_{\cdot 2}}{O_{\cdot \cdot}}$ | <i>O</i> <sub>1</sub> . |
| $A_1$              | $E_{21}=O_{2\cdot}	imes rac{O_{\cdot 1}}{O_{\cdot \cdot}}$ | $E_{22}=O_{2\cdot}	imes rac{O_{\cdot2}}{O_{\cdot\cdot}}$   | <i>O</i> <sub>2</sub> . |
|                    | $a k (O E)^2$   | 0   | <i>O</i>                |

$$\chi^2 = \sum_{i=1}^{a} \sum_{j=1}^{k} rac{(O_{ij} - E_{ij})^2}{E_{ij}} \; \; ext{where} \; \; E_{ij} = O_{i\cdot} imes rac{O_{\cdot j}}{O_{\cdot \cdot}}$$

chi-square distribution with (a-1)(k-1) degree of freedom.

#### Selection of a variable for branching

**Example 6.2.2** Let's examine which variable is better for branching by using the chi-square independence test for the Gender and Credit Status variable in Example 6.2.1.

#### Answer

In the crosstable of the Gender and Purchase status, the distribution of (purchasing group, non-purchasing group) in the entire data is (40%, 60%). The distributions in each Male and female are also the same at (40%, 60%), so the expected frequencies of Male and Female are (4, 6) which are the same as observed frequencies and the chi-square statistic  $\chi^2_{Cender}$  is 0 as follows.

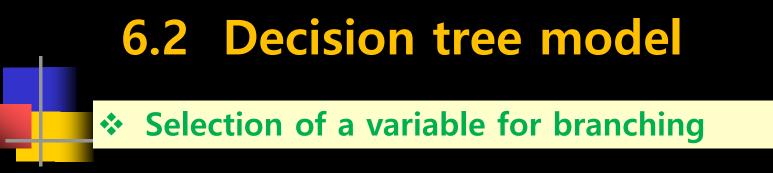

$$\chi^2_{Credit} = rac{(4-4)^2}{4} + rac{(6-6)^2}{6} + rac{(4-4)^2}{4} + rac{(6-6)^2}{6} = 0$$

Therefore, the Gender variable and Purchase status are independent.

In the crosstable of the Credit and Purchase status, the expected frequencies for each Credit status is (4, 6), so the chi-square statistic is as follows.

$$\chi^2_{Credit} = rac{(7-4)^2}{4} + rac{(3-6)^2}{6} + rac{(1-4)^2}{4} + rac{(9-6)^2}{6} = 7.5$$

Therefore, since it is greater than the critical value of  $\chi^2_{1;0.05}$  = 3.841 at the significance level of 5% in the chi-square distribution with the degree of freedom of 1, the Credit variable and Purchase status are not independent. In other words, if the Credit status is known, it contains a lot of information to decide the Purchasing group and the Non-purchasing group. Therefore, the branching is selected by selecting the Credit variable rather than the Gender variable.

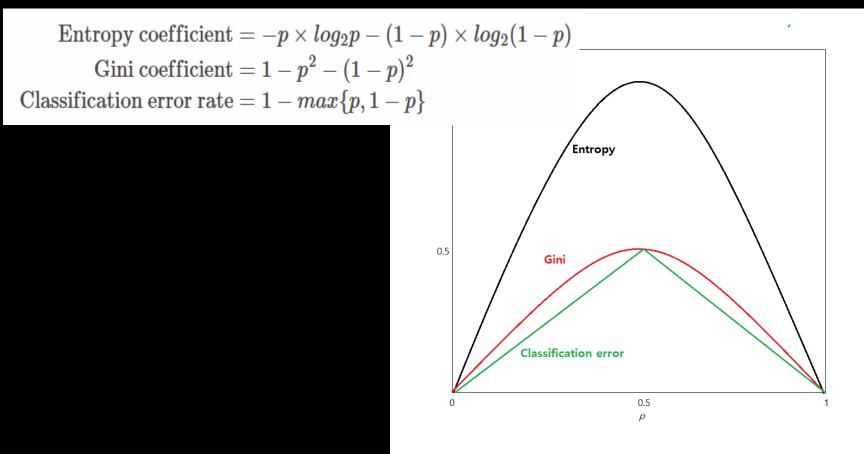

#### B. Entropy, Gini coefficient, and classification error

C

 measure of uncertainty or purity about the distribution of each variable value by group.

#### Selection of a variable for branching

#### B. Entropy, Gini coefficient, and classification error: two groups

#### Selection of a variable for branching

[Example 6.2.3] Find the entropy coefficient, Gini coefficient, and classification error rate for the distribution of the Purchasing group and the Non-purchasing group (40%, 60%) in the entire data. Also, find the entropy coefficient, Gini coefficient, and classification error rate for each Gender and Credit Status, and examine which variable is good for branching.

Table 6.2.5 Uncetainty measures for the distribution of (Purchase, Non-purchase) of entire data

|                | Purchasing<br>group<br>$G_1$ | Non-<br>purchasing<br>group<br>$G_2$ | Total | Uncetainty measures  |
|----------------|------------------------------|--------------------------------------|-------|--|
| Entire<br>data | 6                            | 12                                   | 20    | $egin{aligned} 	ext{Entropy coefficient} &= -0.4 	imes log_2 0.4 - (1-0.4) 	imes log_2 (1-0.4) = 0.9710 \ 	ext{Gini coefficient} &= 1-0.4^2 - (1-0.4)^2 = 0.4800 \ 	ext{Classification error rate} &= 1-max\{0.4,1-0.4\} = 0.4000 \end{aligned}$ |

#### Selection of a variable for branching

Table 6.2.6 Uncetainty measures for the distribution of (Purchase, Non-purchase) of Gender

| Gender | Purchasing group $G_1$ | Non-<br>purchasing<br>group<br>$G_2$ | Total | Uncetainty measures  |
|--------|------------------------|--------------------------------------|-------|--|
| Male   | 4                      | 6                                    | 10    | Entropy coefficient = $-0.4 \times log_2 0.4 - (1 - 0.4) \times log_2 (1 - 0.4) = 0.9710$<br>Gini coefficient = $1 - 0.4^2 - (1 - 0.4)^2 = 0.4800$<br>Classification error rate = $1 - max\{0.4, 1 - 0.4\} = 0.4000$   |
| Female | 4                      | 6                                    | 10    | $\begin{split} \text{Entropy coefficient} &= -0.4 \times log_2 0.4 - (1 - 0.4) \times log_2 (1 - 0.4) = 0.9710\\ \text{Gini coefficient} &= 1 - 0.4^2 - (1 - 0.4)^2 = 0.4800\\ \text{Classification error rate} &= 1 - max\{0.4, 1 - 0.4\} = 0.4000 \end{split}$ |

Table 6.2.7 Uncetainty measures for the distribution of (Purchase, Non-purchase) of Credit Status data

| Credit<br>Status | Purchasing group $G_1$ | Non-<br>purchasing<br>group<br>$G_2$ | Total | Uncetainty measures  |
|------------------|------------------------|--------------------------------------|-------|--|
| Good             | 7                      | 3                                    | 10    | Entropy coefficient = $-0.7 \times log_2 0.7 - (1 - 0.7) \times log_2 (1 - 0.7) = 0.8813$<br>Gini coefficient = $1 - 0.7^2 - (1 - 0.7)^2 = 0.4200$<br>Classification error rate = $1 - max\{0.7, 1 - 0.7\} = 0.3000$ |
| Bad              | 1                      | 9                                    | 10    | Entropy coefficient = $-0.1 \times log_2 0.1 - (1 - 0.1) \times log_2 (1 - 0.1) = 0.4690$<br>Gini coefficient = $1 - 0.1^2 - (1 - 0.1)^2 = 0.1800$<br>Classification error rate = $1 - max\{0.1, 1 - 0.1\} = 0.1000$ |

 Uncertainty of Credit status is higher than Gender

- Combine uncertainty of each variable value
  - => Expected uncertainty

#### Selection of a variable for branching

Table 6.2.8 a imes k frequency table and uncetainty measure of the variable A

| Variable $A$ | Group $G_1$            | Group $G_2$   | <br>Group $G_k$   | Total                          | Uncetainty                |
|--------------|------------------------|---------------|-------------------|--------------------------------|---------------------------|
| $A_1$        | <i>O</i> <sub>11</sub> | $O_{12}$      | <br>$O_{1k}$      | <i>O</i> <sub>1</sub> .        | $I(A_1)$                  |
| $A_2$        | $O_{21}$               | $O_{22}$      | <br>$O_{2k}$      | <i>O</i> <sub>2</sub> .        | $I(A_2)$                  |
|              |                        |               | <br>              |                                |                           |
| $A_a$        | $O_{a1}$               | $O_{a2}$      | <br>$O_{ak}$      | <i>O</i> <sub><i>a</i></sub> . | $I(A_a)$                  |
| Total        | $O_{\cdot 1}$          | $O_{\cdot 2}$ | <br>$O_{\cdot k}$ | О                              | Uncertainty of $A$ $I(A)$ |

Node T uncertainty

$$egin{aligned} I(T) &= -\sum_{j=1} \left( rac{O_{\cdot j}}{O_{\cdot \cdot}} 
ight) \ \log_2 \left( rac{O_{\cdot j}}{O_{\cdot \cdot}} 
ight) \ I(A) &= rac{O_{1\cdot}}{O_{\cdot \cdot}} imes I(A_1) + rac{O_{2\cdot}}{O_{\cdot \cdot}} imes I(A_2) + \dots + rac{O_{a\cdot}}{O_{\cdot \cdot}} imes I(A_a) \end{aligned}$$

- Expected uncertainty of variable A
- Branch into a variable with larger information gain = I(T) I(A)

#### Selection of a variable for branching

Example 6.2.4 In Example 6.2.3, find the information gain for each measure of the Gender and Credit Status variables.

#### Answer

Using the uncertainty values for each measure calculated in Example 6.2.3, the information gain for each measure of the Gender variable is as follows;

$$\begin{aligned} \text{Information gain by entropy} &= 0.9710 - \left(\frac{10}{20} \times 0.9710 + \frac{10}{20} \times 0.9710\right) = 0.0000 \\ \text{Information gain by Gini} &= 0.4800 - \left(\frac{10}{20} \times 0.4800 + \frac{10}{20} \times 0.4800\right) = 0.0000 \\ \text{Information gain by misclassification error} &= 0.4000 - \left(\frac{10}{20} \times 0.4000 + \frac{10}{20} \times 0.4000\right) = 0.0000 \end{aligned}$$

That is, since the Gender variable has the same uncertainty as the current node, there is no information gain for classification that can be obtained by branching. The information gain for the Credit Status variable is as follows;

$$\begin{array}{l} \text{Information gain by entropy} = 0.9710 - \left(\frac{10}{20} \times 0.8813 + \frac{10}{20} \times 0.4690\right) = 0.2958 \\ \text{Information gain by Gini} = 0.4800 - \left(\frac{10}{20} \times 0.4200 + \frac{10}{20} \times 0.1800\right) = 0.1800 \\ \text{Information gain by misclassification error} = 0.4000 - \left(\frac{10}{20} \times 0.3000 + \frac{10}{20} \times 0.1000\right) = 0.2000 \end{array}$$

Therefore, regardless of which measure is used, the Credit Status variable has more information gain than Gender, so it can be said that the Credit Status variable is better for branching at the current node.

#### Selection of a variable for branching

[Example 6.2.5] When we surveyed 20 customers who visited a computer store, 8 customers purchased a computer (Purchasing group, and 12 customers did not purchase a computer (Non-purchasing group). The survey included variables such as gender, age, monthly income, and credit status of these 20 customers as well as Purchase status as shown in Table 6.2.9.

Note that all variables are surveyed as categorical variables such as (Female, Male) for gender, (20s, 30s) for age, (GE2000, LT2000) for income, (Bad, Fair, Good) for credit status, and (No, Yes) for Purchase status.

#### Selection of a variable for branching

| Table 6.2.9 Survey of customers on gender, age, income, credit status and purchase status |        |     |                             |        |          |  |  |
|---|--------|-----|-----------------------------|--------|----------|--|--|
| Number  | Gender | Age | Income<br>(unit 10,000 won) | Credit | Purchase |  |  |
| 1   | Male   | 20s | LT2000                      | Fair   | Yes      |  |  |
| 2   | Female | 30s | GE2000                      | Good   | No       |  |  |
| 3   | Female | 20s | GE2000                      | Fair   | No       |  |  |
| 4   | Female | 20s | GE2000                      | Fair   | Yes      |  |  |
| 5   | Female | 20s | LT2000                      | Bad    | No       |  |  |
| 6   | Female | 30s | GE2000                      | Fair   | No       |  |  |
| 7   | Female | 30s | GE2000                      | Good   | Yes      |  |  |
| 8   | Male   | 20s | LT2000                      | Fair   | No       |  |  |
| 9   | Female | 20s | GE2000                      | Good   | No       |  |  |
| 10  | Male   | 30s | GE2000                      | Fair   | Yes      |  |  |
| 11  | Female | 30s | GE2000                      | Good   | Yes      |  |  |
| 12  | Female | 20s | LT2000                      | Fair   | No       |  |  |

- E = {data set}
  - F = {Gender, Age, Income, Credit}
  - Target variable = Purchase
  - Stopping rule
    - min number of data in leaf  $\leq = 5$
    - all data belong to a group
- Uncertainty of root node T Entropy coefficient of (8/20, 12/20)

 $I(T) = -0.4 \times \log_2 0.4 - 0.6 \times \log_2 0.6 = 0.9710$

#### Example of decision tree

## Categorization of a continuous variable

[Example 6.2.6] we want to divide the monthly income into two categories. What boundary value of the income is reasonable to divide for classification?

|          | Table 6. | 2.14 Su | rvey of c | ustome | rs on inc | ome and | d purcha | se statu | S   |     |
|----------|----------|---------|-----------|--------|-----------|---------|----------|----------|-----|-----|
| Purchase | Ν        | Ν       | Ν         | Y      | Y         | Y       | Ν        | Ν        | Ν   | Ν   |
| Income   | 100      | 120     | 160       | 180    | 186       | 190     | 210      | 250      | 270 | 300 |

#### <Answer>

 Using the Gini coefficient as the uncertainty measure, the expected Gini coefficient when the middle value is 110 calculated as follows;

$$\frac{1}{10} \times \left\{ 1 - (\frac{1}{1})^2 - (\frac{0}{1})^2 \right\} + \frac{9}{10} \times \left\{ 1 - (\frac{6}{9})^2 - (\frac{3}{9})^2 \right\} = 0.4000$$

## Categorization of a continuous variable

#### <Answer of Example 6.2.6>

| Table 6.2.15 Expected | Table 6.2.15 Expected Gini coefficient using the middle value of two adjacent incomes |              |       |       |                           |                    |       | Actual | group        |       |                           |  |

|                    | Total |              |       | 10    | 0.400                     |

## 

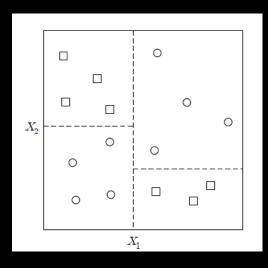

- Decision tree models can have an overfitting problem;
  - Classifying training data well but not good for testing data.
- Pruning is one way to solve the problem of overfitting.
  - Pre-pruning is to examine the appropriateness of the division using chi-square tests and information gain
  - A threshold value must be set, determined by researcher.
  - Post-pruning is a method of removing branches from a completed tree.
  - Pre-pruning and post-pruning are sometimes used in combination.

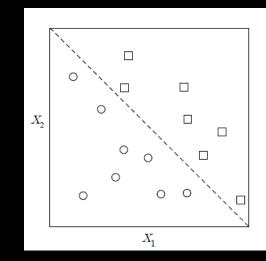

## Characteristics of decision tree

- The decision tree model is a nonparametric method that does not assume the distribution function of each group.
- Decision trees are easy to explain to anyone.
- Since the calculations are not complicated, they can be applied to large amounts of data.
- They are not very sensitive to noisy data.
- Since they use a local optimization search algorithm, they may not find the overall optimal decision tree.
- Similar small trees may appear repeatedly.

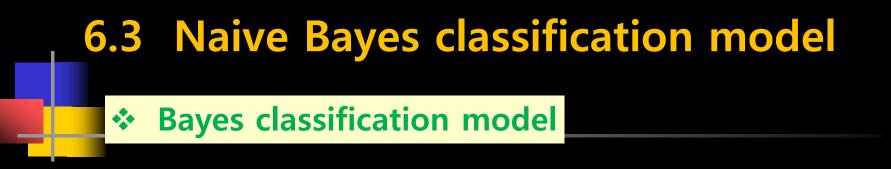

## Characteristics of decision tree

• A decision tree examines only the conditions for one variable in one node. Therefore, the classification rule of the decision tree partitions the entire decision space into straight lines parallel to the coordinate axes

Not easy to split by a decision tree.

When the prior probability of being classified into each group and the likelihood probability of each group are known, the Bayes classification model is a method of classifying data into groups with high probability by calculating the posterior probability using Bayes theorem,

### Bayes classification model

[Example 6.3.1] (Classification by prior probability)

When 20 customers who visited a computer store were surveyed, 8 customers purchased a computer, and 12 customers did not purchase a computer. Based on this information, classify a customer who visited this store on a day whether he would purchase a computer or not.

#### <Answer>

- Among the 20 customers who visited the store, only 8 (40%) purchased a computer, and 12 (60%) did not purchase a computer.
- The probability of the purchasing group is 40% and non-purchasing group is 60% are called prior probabilities.
- Since the probability of the non-purchasing group is higher than the purchasing group, it is reasonable to classify a customer into the non-purchasing group.

### Bayes classification model

[Example 6.3.2] (Classification by posterior probability) Suppose there are 10 customers in their age 20's among 20 customers and 10 customers in their age 30s. Among the 8 purchasing groups, 2 customers in their age 20s and 6 are in their age 30's. If a customer who visited the store on a day is in his age 20's, classify the customer whether he purchases the computer or not by calculating the posterior probability.

#### <Answer>

| Table 6.3.1 crosstable on Age by Purchasing status |                        |                            |       |  |  |  |  |  |
|--|------------------------|----------------------------|-------|--|--|--|--|--|
| Age  | Purchasing group $G_1$ | Non-purchasing group $G_2$ | Total |  |  |  |  |  |
| 20's   | 2                      | 8                          | 10    |  |  |  |  |  |
| 30's   | 6                      | 4                          | 10    |  |  |  |  |  |
| Total  | 8                      | 12                         | 20    |  |  |  |  |  |

### Bayes classification model

#### <Answer of Example 6.3.2>

Posterior probability;

$$P(G_{1}|x) = \frac{P(G_{1}) \times P(x|G_{1})}{P(G_{1}) \times P(x|G_{1}) + P(G_{2}) \times P(x|G_{2})} = \frac{\frac{8}{20} \times \frac{2}{8}}{\frac{8}{20} \times \frac{2}{8} + \frac{12}{20} \times \frac{8}{12}} = 0.2$$

$$P(G_{2}|x) = \frac{P(G_{2}) \times P(x|G_{2})}{P(G_{1}) \times P(x|G_{1}) + P(G_{2}) \times P(x|G_{2})} = \frac{\frac{12}{20} \times \frac{8}{12}}{\frac{8}{20} \times \frac{2}{8} + \frac{12}{20} \times \frac{8}{12}} = 0.8$$

 Posterior probability that a customer belongs to non-purchasing group is 0.8, which is higher than purchasing group 0.2, this customer is classified as a non-purchasing group.

**Bayes classification rule by posterior probability** 

'If  $P(G_1|X) \ge P(G_2|X)$ , classify data as  $G_1$ , otherwise classify as  $G_2$ '

'If  $\frac{P(X|G_1)}{P(X|G_2)} \ge \frac{P(G_2)}{P(G_1)}$ , classify data as  $G_1$ , otherwise classify as  $G_2$ '

Bayes Classification - multiple groups

'If  $P(G_k)f_k(\boldsymbol{x}) \geq P(G_i)f_i(\boldsymbol{x})$  for all  $k \neq i$ , classify  $\boldsymbol{x}$  into group  $G_k$ '

### Naive Bayes classification model for categorical data

#### [Example 6.3.3]

Consider a survey of 20 customers at a computer store on age (X1), monthly income (X2), credit status (X3) and their purchasing status as shown in Table 6.3.2. Note that the age transformed into '20s' and '30s' as categorical, income into 'LT2000' and 'GE2000', and credit status into 'Bad', 'Fair' and 'Good'.

| Table 6.3.2 Survey of customers on age, income, credit status and purchasing status |     |                      |        |          |  |  |  |  |  |
|---|-----|----------------------|--------|----------|--|--|--|--|--|
| Number  | Age | Income<br>(unit USD) | Credit | Purchase |  |  |  |  |  |
| 1   | 20s | LT2000               | Fair   | Yes      |  |  |  |  |  |
| 2   | 30s | GE2000               | Good   | No       |  |  |  |  |  |
| 3   | 20s | GE2000               | Fair   | No       |  |  |  |  |  |

#### Naive Bayes classification model for categorical data •••

#### <Answer of Example 6.3.3>

if variables, age, income, and credit status, can be assumed to be independent, the onedimensional likelihood probability distribution of each variable is used approximately to estimate the multidimensional likelihood probability distribution as follows.

 $P(\mathbf{X} = (X_1, X_2, X_3) \mid G_i) \approx P(X_1 \mid G_i) P(X_2 \mid G_i) P(X_3 \mid G_i)$ 

 $P(\boldsymbol{x} = (30s, LT2000, Fair) \mid G_1) \approx \frac{6}{8} \times \frac{2}{8} \times \frac{4}{8} = 0.0938$ 

 $P(\boldsymbol{x} = (30s, LT2000, Fair) \mid G_2) \approx \frac{4}{12} \times \frac{4}{12} \times \frac{7}{12} = 0.0648$ 

#### Posterior probability

$$\begin{split} P(G_1|\boldsymbol{x}) &= \frac{P(G_1) \times P(\boldsymbol{x}|G_1)}{P(G_1) \times P(\boldsymbol{x}|G_1) + P(G_2) \times P(\boldsymbol{x}|G_2)} \\ &= \frac{0.4 \times 0.0938}{0.4 \times 0.0938 + 0.6 \times 0.0648} = 0.4911 \\ P(G_2|\boldsymbol{x}) &= \frac{P(G_2) \times P(\boldsymbol{x}|G_2)}{P(G_1) \times P(\boldsymbol{x}|G_1) + P(G_2) \times P(\boldsymbol{x}|G_2)} \\ &= \frac{0.4 \times 0.0938}{0.4 \times 0.0938 + 0.6 \times 0.0648} \end{split}$$

$$= \frac{0.00 \times 0.0010}{0.4 \times 0.0938 + 0.6 \times 0.0648} = 0.5089$$

~ ~ ~ ~ ~

### Stepwise variable selection

- Naive Bayes classification can be applied by categorizing the continuous variables.
- Forward selection selects a variable with the highest information gain using the uncertainty measures.
  - Add another variable with next highest information gain
- Backward elimination includes all variables and selects a variable to remove which improve classification accuracy.
  - Continue removing a variable until there is no improvement in classification accuracy.
- A stepwise method selects variables using the forward selection method while examining whether the variables

## Evaluation of a classification model

Table 6.4.1 Table for the test results of the actual group and the classified group

|              |       | Classifie |          |                   |
|--------------|-------|-----------|----------|-------------------|
|              |       | $G_1$     | $G_2$    | Total             |
| Actual group | $G_1$ | $f_{11}$  | $f_{12}$ | $f_{11} + f_{12}$ |
|              | $G_2$ | $f_{21}$  | $f_{22}$ | $f_{21} + f_{22}$ |
|              | Total |           |          | n                 |

$$egin{aligned} ext{Accuracy} &= rac{f_{11}+f_{22}}{n} \ ext{Error rate} &= rac{f_{12}+f_{21}}{n} \ \end{aligned}$$

Sensitivity = 
$$\frac{f_{11}}{f_{11} + f_{12}}$$
  
Specificity =  $\frac{f_{22}}{f_{21} + f_{22}}$   
Precision =  $\frac{f_{11}}{f_{11} + f_{21}}$   
Accuracy =  $\frac{f_{11} + f_{12}}{n}$ (Sensitivity) +  $\frac{f_{21} + f_{22}}{n}$ (Specificity)

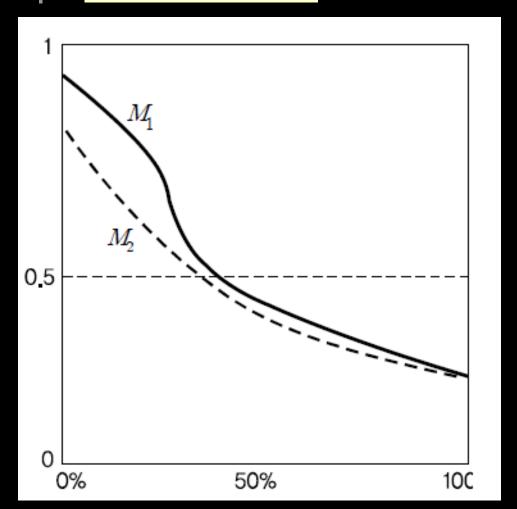

#### Lift chart

- Assume that results of a classification model are expressed as continuous values, posterior probability.
   large values means a high probability being classified as group 1.
- Rate of group 1 among the entire data is called the baseline response (%).
- Arrange data in descending order of posterior probability, observe the top 10% of the data. Rate of classifying actual group 1, as group 1 will be high. Upper 10% response.
- Upper 10% response rate compared to the baseline response rate is called the lift or improvement of top 10%

### Lift chart

 Since model M1 classifies group 1 more accurately than model M2 at each percentile of data, so model M1 can be said to be better than M2.

Confusion matrix

- Confusion matrix is often used to determine the cut-off value of the posterior probability to determine the group.
- Generally, the cut-off value for determining the group is mainly accuracy, but sensitivity and specificity should also be carefully examined.

### Confusion matrix

| Number | Posterior<br>probability | Number<br>of data | f <sub>11</sub> | f <sub>12</sub> | f <sub>21</sub> | f <sub>22</sub> | Accuracy | Sensitivity | Specificity |

## ROC graph

- ROC graph;
  - (1 specificity) on x-axis and (sensitivity) on y-axis

(Sensitivity): true positive rate (TPR)

- (1 specificity): false positive rate (FPR)
- A point on the ROC graph represents the result of a classification model when a critical value of the posterior probability is used.
- ROC graph examines the changes in FPR and TPR when we change the critical value.

ROC graph

- (FPR=0, TPR=0) classifies all points into group 2,
- (FPR=1, TPR=1) classifies all data into group 1
- (FPR=0, TPR=1) does not misclassify group 2 into group 1 and correctly classifies all group 1 data.
- Ggod classification model should have the classification results located in the upper left corner of the ROC graph.
- Diagonal line shows an exceptional model in which both the TPR and FPR ratios are the same, group 1 data is classified into group 1 with probability p (TPR = p), and group 2 data is also classified into group 1 with probability p (FPR = p).

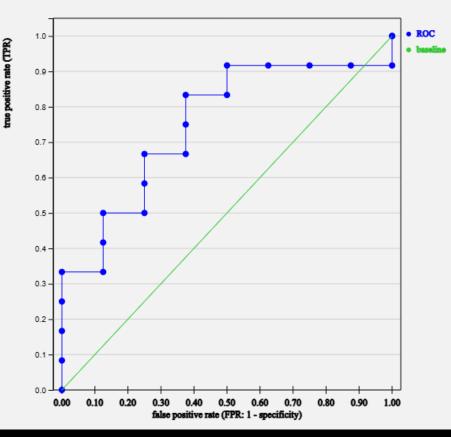

Model M1 is located upper on the left than model M2. M1 is better than model M2. 60

ROC graph

Receiver operating characteric (ROC) plot for training data

### Comparison of classification models

Confidence interval for accuracy

$$P(-Z_{rac{lpha}{2}} < rac{\hat{p}-p}{\sqrt{p(1-p)}} < Z_{rac{lpha}{2}}) = 1-lpha$$

$$rac{(2n imes\hat{p}+Z_{rac{lpha}{2}}^2)~\pm~Z_{rac{lpha}{2}}\sqrt{Z_{rac{lpha}{2}}^2+4n imes\hat{p}-4n imes\hat{p}^2}}{2n+2Z_{rac{lpha}{2}}^2}$$

Comparison of two classification models
 confidence interval of the accuracy difference

$$(\hat{p}_1 - \hat{p}_2) ~\pm~ Z_{rac{lpha}{2}}~ \sqrt{rac{\hat{p}_1(1-\hat{p}_1)}{n_1} + rac{\hat{p}_2(1-\hat{p}_2)}{n_2}}$$

Generalized erro considering model overfitting

$$\begin{split} e_g(T) &= \frac{\sum_{i=1}^k [e(t_i) + \Omega(t_i)]}{\sum_{i=1}^k n(t_i)} \\ &= \frac{e(T) + \Omega(T)}{\sum_{i=1}^k n(t_i)} \end{split}$$

 $\Omega(t_i)$  is the penalty term in each node  $t_i$ .

e(T) is the overall error rate,  $\Omega(T)$  is the overall penalty term

## Summary

- Probability:
  - Classical and relative frequency definition
  - Addition and multiplication rules
  - Bayes theorem
- Random variable and probability distribution:
  - Random variable is a function from a sample space to real number
  - Binomial distribution, normal distribution
  - Multiivariate normal distribution
- Estimation of a distribution:
  - Maximum likelihood estimation

## Thank you !!!
